2. Scenario: You are a data analyst working for a company that sells products online. You have been tasked with analyzing the sales data for the past month. The data is stored in a NumPy array.

Question: How would you find the average price of all the products sold in the past month? Assume 3x3 matrix with each row representing the sales for a different product

AIM:

To calculate the average price of products sold during a month using NumPy arrays.

PROCEDURE:

1. Import the NumPy library.
2. Create a 3×3 array representing the sales data of three products.
3. Use np.mean() to calculate the average of all array elements.
4. Display the average price.

PROGRAM CODE:

```
import numpy as np

sales = np.array([

   [100, 200, 300],

   [150, 250, 350],

   [200, 300, 400]

])

average_price = np.mean(sales)

print("Average Price:", average_price)
```

INPUT:

[[100, 200, 300],

[150, 250, 350],

[200, 300, 400]]

OUTPUT:

```
import numpy as np

sales = np.array([
    [100, 200, 300],
    [150, 250, 350],
    [200, 300, 400]
])

average_price = np.mean(sales)

print("Average Price:", average_price)
```

```
Average Price: 250.0
```

RESULT:

Thus, the average price of all the products was calculated using NumPy. The average price is 250.0.
